

Hey Pres! One of the things I have always liked about WRB Zones is that a zone remains open until certain conditions are met. For example, I like to close a WRB zone after there is price action above and below the zone. More specifically, a full candle body above and a full candle body below. Unless the candle in question is directly involved in the entry signal pattern. How do you know when a Zone is no longer "Good"? This is one of the things I never liked about "trigger numbers". I never knew how long a particular trigger was valid. If they continue...

Hey HG my friend...

I am not trading WRB's in the sense that you trade them. I have studied that a bit and have a rough understanding of it but this is WRB zones from H to L and based on UHV. I do not consider a zone void when it fills, I consider a zone void when SM are no longer active in the zone or when the zone is replaced by a new zone. Messy, nope not really. Each zone is 3 levels a H, 50% and L. If a newer higher volume zone prints in the same area I remove the old zone. I manage my zones and levels to keep things neat and tidy and to make things the most trade-able.

Do I still have a 4 hour zone on from 6 months ago? Quite well could have if it hasn't been replaced / voided and I can almost guarantee that when price returns to that action zone 6 months later there will be reactions (or a news driven WRB blow through making a new zone).

Yes any trade can be taken within a zone for basic VZA. If I see sellers at the high of a UHV zone I will go short back down to at least 50%.

I do also trade S&D zones and I find that the UHV zones often align with these and this can play a factor in my trading decisions. Again though if I see sellers at the high of even a "demand" zone I will go short if I have room back down to the next clear buying level. 4 hour WRB UHV zones give the room to do this. Grab some pips short and then get back in long when the SM start buying again at lower prices.

Supply and demand and how this is viewed within VSA really confuses me now as I have grown and continued my studies in other trading subjects. A test bar for example is "testing" for sellers. Who is selling at these lower prices that are being "tested". Are the SM selling at prices lower than current price? I don't think SM are making any money by selling at lower prices so who are they testing for to see if they are selling? The theory is they are testing and if no sellers are found price is free to go up. That is also backwards thinking because sell orders under current price are not an obstacle for rising prices, sell orders higher up are.

Anyway HG I hope that answered your questions.
